## 2. Scope of Document:

The description of the XRT bad pixels is contained in two files in CALDB. The file swxonboardbp*.fits (from here forward swxonboardbp) contains all bad pixels uploaded to the instrument and contained in the onboard bad pixel map, the second file, swxbadpix*.fits (from here forward swxbadpix), contains both the pixels loaded onboard and some additional pixels which should be ignored by the ground processing. These two
files have three extensions describing the bad pixels for each of the following modes: Photon Counting (PC) Mode, Windowed Timing (WT) Mode and Imaging Mode. For each mode, each bad pixel identified in the CCD array is described in RAWX and RAWY co-ordinates relative to each of the two CCD amplifiers. This document contains a description of the latest updates installed in the XRT pipeline bad pixel calibration file and in the XRT on-board bad pixel table.

## 3. Overview of Changes Incorporated in this Revision:

New hot pixels have been identified from analysis of on-orbit data and were uploaded to the XRT bad pixel map on April 12 ${ }^{\text {th }} 2006$, June $15^{\text {th }} 2006$, September $29^{\text {th }} 2006$ and October $17^{\text {th }} 2006$. In addition, 2 pixels which had previously been identified as hot pixels were recognized (through analysis of on-orbit data) to have returned to normal function. On June $15^{\text {th }} 2006$, these 2 pixels were removed from the XRT bad-pixel map.

## 4. Identification of Hot, Bad and Flickering Pixels:

The XRT CCD contains several dead, hot or warm pixels. Dead pixels are those that do not effectively register charge for X-rays which strike them. Hot pixels are those that produce noise levels that are too high to use effectively at all temperatures. Warm pixels are those that produce a higher noise level than normal pixels but which are still able to be used for science observations below particular XRT CCD temperatures. In the case of warm and hot pixels, the anomalous behavior is due to charge traps in the lattice, which cause the pixels to overproduce dark current as compared to normal pixels. For temperatures high enough that the dark current charge produced exceeds the event threshold, these warm pixels are identified as X-ray events by the flight software. For the XRT CCD, it appears that most of the charge traps which produce warm pixels are frozen out below temperatures of about $-54^{\circ} \mathrm{C}$. Furthermore, the onboard software allows an upload of hot pixel co-ordinates to a bad pixel map, so that they may be eliminated from the count rate evaluation and removed from the telemetry stream. The ground processing software task xrthotpix also determines hot pixels as pixels persistent from frame to frame of an observation. The hot pixel upload is thus a trade-off between mitigating the effects of the warm pixels at high temperatures and reducing the effective area of the CCD at lower temperatures for which the effects of the warm pixels are largely frozen out. It should be noted that the effects of a particular warm pixel are most severe in PC mode where the readout time is the longest. In the higher resolution timing mode (WT), the contribution of particular warm pixels are much less significant due to the much faster clocking of the CCD.

The XRT bad pixel list at the time of launch consisted of one partial dead column (composing 209 out of 600 pixels in one column) and one additional bad pixel, defined from ground calibration data collected at $-100^{\circ} \mathrm{C}$. At the actual on-orbit operating temperature of XRT, several more hot pixels have become apparent. The number of noise events detected in each XRT pixel follows an exponential function with respect to CCD temperature. For most pixels the function remains below the XRT event threshold of 80 DN at temperatures up to $-54{ }^{\circ} \mathrm{C}$. A small fraction of the pixels do exceed the event
threshold at temperatures colder than $-54^{\circ} \mathrm{C}$; these are designated as warm pixels. The most extreme of these 'warm pixels' have been uploaded to the XRT and added to the CALDB bad pixel list.

Table 2 shows the additional pixels, which are listed in the swxbadpix CALDB product to define the region of the 'burn-spot' on the XRT CCD. The burn-spot is a region of anomalously warm pixels slightly off-center from the XRT boresight which produce a noticeable excess number of events above temperatures of approximately $-60^{\circ} \mathrm{C}$.

A warm-pixel-tracking algorithm has been developed to monitor the performance of all pixels on the XRT CCD throughout normal daily operations of the instrument. Most XRT observations are performed in PC mode. In this mode, each event recorded by the CCD above the event threshold is position tagged and telemetered to the ground. Because typical noise levels are 0.01 counts per second over the entire CCD the likelihood of any individual pixel recording multiple events during the course of a single orbit is extremely low unless the events recorded are due to thermally generated charge produced by the pixel itself. Thus, a search is performed on each orbit of PC data and pixels which record events in greater than $10 \%$ of the PC mode frames are collected. Bright sources such as gamma ray bursts and other observing targets do not cause false identification of hot pixels because multiple targets (typically 4-6) are observed during a single orbit at slightly different locations on the XRT CCD due to the $\sim 3$ arcminute pointing accuracy of the spacecraft.

## 5. Scientific Impact of Bad Pixels:

The masked out pixels may occur near the center of the CCD, so that there is a significant chance that the point spread function of the intended target may fall partially on the masked out columns or other hot pixels. The hot pixels which are defined in the CALDB swxonboardbp files are excluded onboard from the telemetry and the pixels defined in swxbadpix are not processed by the XRTPIPELINE software. In XRTPIPELINE versions prior to version 0.9 .9 (released 10-November-2005), no exposure map correction is made to account for the decreased collecting area in such a situation. Thus any user wishing to perform a proper exposure map correction on their data must be aware of the masked out pixels/columns identified in this calibration product and adjust their data accordingly. XRTPIPELINE version 0.9.9 and after correctly account for the exposure.

As a result of the re-inventory of bad pixel uploads throughout the mission (performed prior to the release of document SWIFT-XRT-CALDB-01_v5 - see that document for further details), bad pixel information contained in this CALDB release is different and more accurate than the information contained in releases previous to 27-April-2006. The changes made are outlined in Section 9.

## 6. Caveat Emptor:

XRT bad pixels are highly temperature dependent and as a result, some pixels which are not contained in these CALDB products may appear anomalous at higher temperatures than those used to identify bad pixels for inclusion in the CALDB. Hot pixels are
identified at temperatures at or below $-54{ }^{\circ} \mathrm{C}$, so data taken at temperatures above this level may show additional bad pixels. The XRTPIPELINE task xrthotpix, identifies and eliminates these pixels from an observation.

## 7. Expected Updates:

It is expected that radiation damage during the orbital lifetime of Swift will degrade the XRT CCD by introducing more bad pixels. Periodic updates to the Bad Pixel table files will be made to account for these changes.

## 8. Pre-launch Bad Pixel Table:

Prior to launch the XRT CCD bad pixels consisted of 1 partial bad column (209 pixels in extent) and 1 other hot pixel. In CALDB bad pixel files after the $27^{\text {th }}$ May $2005^{*}$, the dead column is marked only in the on-ground bad pixel table and the single bad pixel is included in swxbadpix and swxonboardbp files, mapped through both the A and B amplifier. These are shown in Table 1.

Table 1: Original pre-launch bad pixel and dead pixel list

| RawX | RawY | AMP | Y-extent |
| :---: | :---: | :---: | :---: |
| 453 | 391 | 1 | 209 |
| 146 | 391 | 2 | 209 |
| 453 | 390 | 1 | 1 |
| 146 | 390 | 2 | 1 |

## 9. On-orbit Bad Pixel Uploads:

## May $27^{\text {th }} 2005$

Between the $25^{\text {th }}$ and $27^{\text {th }}$ May 2005, new flight software was uploaded to the XRT, such that in PC Mode, a source countrate is only evaluated within a small window in the centre of the CCD. This means that only the bad pixels within the central 200x200 pixel window need to be uploaded to the flight software. The hot pixels in the outer region of the CCD are telemetered and identified either in the swxbadpix file or from running the xrthotpix task in the XRT Pipeline. Prior to this time all the bad pixels in the $600 \times 600$ pixel array had to be identified.

An isolated event on May $27^{\text {th }} 2005$, possibly a micrometeorite strike to the XRT detector or extremely high-energy charged particle, damaged several additional pixels and

[^0]columns. It is possible that the severity of the excess charge seen in the pixels affected by the May $27^{\text {th }}$ event may change over time. The state of these warm/hot pixels will be tracked throughout the course of the mission to note any changes in state (for better or worse) so that they may be added or removed from the bad pixel lists accordingly. 4 hot columns were uploaded for PC Mode and Imaging mode and 4 hot columns were identified in the onboard WT bad pixel row. Bad pixels from the $27^{\text {th }}$ May 2005 are shown in Table 4, Table, Table and Table.

## $9^{\text {th }}$ June 2005

From observing the hot columns uploaded to the XRT on the $27^{\text {th }}$ May for PC mode, WT Mode and Imaging Mode, it became apparent that there was an off-set of one column between PC mode and WT Mode (SWIFT-XRT-CALDB-08). The hot columns identified onboard were corrected for this fact on the $9^{\text {th }}$ June 2005 (Table 4; Table; Table ; Table ).

## 18 ${ }^{\text {th }}$ January 2006

At temperatures above $-56^{\circ} \mathrm{C}$, the hot columns in the center of the CCD were found to be overflowing into additional columns in PC Mode and causing mode-switching between PC Mode and WT Mode. To minimize this effect, a partial column was uploaded in PC Mode (Table 5; Table ; Table ; Table ).
$9^{\text {th }}$ February 2006
Eleven bad pixels were uploaded to the onboard bad pixel map for PC Mode and Imaging Mode and an additional hot column was uploaded to the WT Mode bad pixel row. These pixels are listed in Table 6, Table, Table and Table .

## 12 ${ }^{\text {th }}$ April 2006

Eight bad pixels were uploaded to the onboard bad pixel map for PC Mode and Imaging Mode. These pixels are listed in Table 6, Table , Table and Table .

## $15^{\text {th }}$ June 2006

Nine bad pixels were uploaded to the onboard bad pixel map for PC Mode and Imaging Mode and two pixels were unmasked from the onboard bad pixel map for PC and Imaging Mode. These pixels are listed in Table 6, Table, Table and Table .

## 29 ${ }^{\text {th }}$ September 2006

Thirteen bad pixels were uploaded to the onboard bad pixel map for PC Mode and Imaging. These pixels are listed in Table 6, Table , Table and Table .

## 17 ${ }^{\text {th }}$ October 2006

Five bad pixels were uploaded to the onboard bad pixel map for PC Mode and Imaging Mode. These pixels are listed in Table 6, Table , Table and Table .

## 10. CALDB Updates

## $12^{\text {th }}$ October 2005

The XRT on-board and ground bad pixel lists swxonboardbp20010101v005.fits and
swxbadpix20010101v005.fits contain the partial dead column, the hot-spot region and several hot pixels that were uploaded to the XRT. Hot columns and hot pixels due to micrometeroid damage were not included in these files.

## $24^{\text {th }}$ April 2006

The XRT on-board and ground bad pixel lists identified in Section 1 , include the $12^{\text {th }}$ October update covering launch until $27^{\text {th }}$ May 2005 and the re-inventory all of the bad pixels and also the $9{ }^{\text {th }}$ February upload to the XRT.
A re-inventory of all bad pixels that have appeared from launch through $9^{\text {th }}$ February 2006 has been done to correct discrepancies that existed between the true bad pixel list and the values that had been loaded into the CALDB tables. Discrepancies were found in both the positions of some bad pixels and in the exclusion times (time/date at which a particular bad pixel is designated as having become unusable) of some bad pixels. The current bad pixel lists contained in the CALDB represent the best and most accurate catalog of bad pixels throughout the history of the mission. This catalog is detailed in Table 3-Table below. Table 3-Table 6 show the PC/Image mode bad pixels in the ground bad pixel catalog. Table -Table show the PC/Image mode bad pixels in the onboard bad pixel catalog. Table -Table show the WT bad pixels in the ground bad pixel catalog. Table -Table show the WT bad pixels in the onboard bad pixel catalog. All bad pixels are listed only showing their positions as read out through amplifier \#1, though the CALDB products also contain the complementary bad pixel entry for the detector as read out through amplifier \#2. The 'Time' column in the tables below represents the mission elapsed time (MET) at which the pixel is first considered as bad. 'RAWX' and 'RAWY' identify the position of the bad pixel in raw detector coordinates (see Appendix for an explanation of the various XRT coordinate systems). 'Amp' defines to which amplifier the current CALDB row corresponds (only Ampl entries are listed below for brevity, though both Amp1 and Amp2 entries are contained in the CALDB). 'Type' defines whether the CALDB row refers to an individual bad pixel (1) or a partial or full bad column (2). 'Yextent' describes the length of the column of detectors masked out in cases where Type $=2$ (starting at the RawX, RawY position and extending in the + RawY direction).

In the current release of the CALDB, 8 badpixel files are included, 4 ground and 4 onorbit. The reason for having 4 files of each type is that the XRTPIPELINE does not currently read the 'Time' column of the CALDB file to identify whether a particular bad pixel should be applied to a given dataset. Because this functionality is not yet included, a work-around method has been developed using 4 files of each type whereby the filenames are used to select between the appropriate bad pixel table to use for each time period. When the functionality to read the 'Time' column from the CALDB tables is included in the XRTPIPELINE in a future release, only one CALDB file of each type will be required and the others will be removed at that time.

## $8^{\text {th }}$ November 2006

The XRT on-board and ground bad pixel lists identified in Section 1, including the $12^{\text {th }}$ April 2006, $15^{\text {th }}$ June 2006, $29^{\text {th }}$ September 2006 and $17^{\text {th }}$ October 2006 updates.

## Appendix - Coordinate Transformation Algorithms

We copy here the coordinate transformation algorithms from XRT-PSU-037, XRT Science Algorithms for the convenience of the reader:

- $\mathrm{X}_{\text {raw }}, \mathrm{Y}_{\text {raw }}$ : These are raw detector coordinates of the image area. Pixels are numbered ( $0: 599,0: 601$ ) and are relative to the output amplifier. The conversion from chip to raw coordinates is:

$$
X_{\text {raw }}=X_{\text {chip }}-6 \quad \text { for }\left(6 \leq X_{\text {chip }} \leq 605\right)
$$

$$
\mathrm{Y}_{\text {raw }}=\stackrel{2.1}{\mathrm{Y}_{\text {chip }}}
$$

This is the coordinate system reported by the flight software in Low Rate Photodiode Mode and Windowed Timing Mode.

- $\mathrm{X}_{\text {det }}, \mathrm{Y}_{\text {det }}$ : These are focal plane coordinates of image area in pixels, numbered ( $1: 600,1: 602$ ), so they can be compared with pixel numbers from image display software like $d s 9$. Pixels are numbered relative to physical location on the CCD, not to amp readout. The conversion from raw to det coordinates is:
- Amp 1:
2.2

$$
\begin{gathered}
\mathrm{X}_{\text {det }}=\mathrm{X}_{\text {raw }}+1 \\
\mathrm{Y}_{\text {det }}=\mathrm{Y}_{\text {raw }}+1
\end{gathered}
$$

- Amp 2:
2.3

$$
\begin{aligned}
& \mathrm{X}_{\text {det }}=600-\mathrm{X}_{\text {raw }} \\
& \mathrm{Y}_{\text {det }}=\mathrm{Y}_{\text {raw }}+1
\end{aligned}
$$

- $\mathrm{X}_{f o c}, \mathrm{Y}_{f o c}$ : These are focal plane coordinates in millimeters from the center of the detector. The conversion from det to foc coordinates is

$$
\begin{aligned}
\mathrm{X}_{f o c}= & \mathrm{A}+\mathrm{K} * \mathrm{X}_{d e t} \\
& 2.4 \\
\mathrm{Y}_{f o c}= & \mathrm{B}+\mathrm{K}^{*} \mathrm{Y}_{d e t}
\end{aligned}
$$

where

$$
\begin{aligned}
& \mathrm{K}=0.0400=\text { pixel scale in } \mathrm{mm} / \text { pixel } \\
& \mathrm{A}=-300.5 * \mathrm{~K}=\text { pixel offset in } \mathrm{mm} \\
& \mathrm{~B}=-300.5 * \mathrm{~K}=\text { pixel offset in } \mathrm{mm}
\end{aligned}
$$

[^0]:    *For the bad pixel files prior to $27^{\text {th }}$ May 2005 the dead columns is listed in both swxonboardbp and swxrtbadpix
