A detailed Suzaku study of an evolved SNR, the Cygnus Loop. The background is a dark, star-filled field with a prominent, glowing, reddish-pink and blue nebula structure in the center, resembling a swan's neck and head. The text is overlaid in a bright yellow font with a blue outline.

A breath of fresh air from the old Swan

# The Cygnus Loop Observations with Suzaku & XMM-Newton

| Satellite  | Number | Obs. Date           | Eff. Exposure Time |
|------------|--------|---------------------|--------------------|
| Suzaku     | 72     | Nov 2005 – Jun 2011 | 1676.7 ks          |
| XMM-Newton | 9      | Nov 2002 – May 2006 | 93.5 ks            |

We completely covered this remnant with Suzaku (and XMM) by the AO6 phase.

# Outline

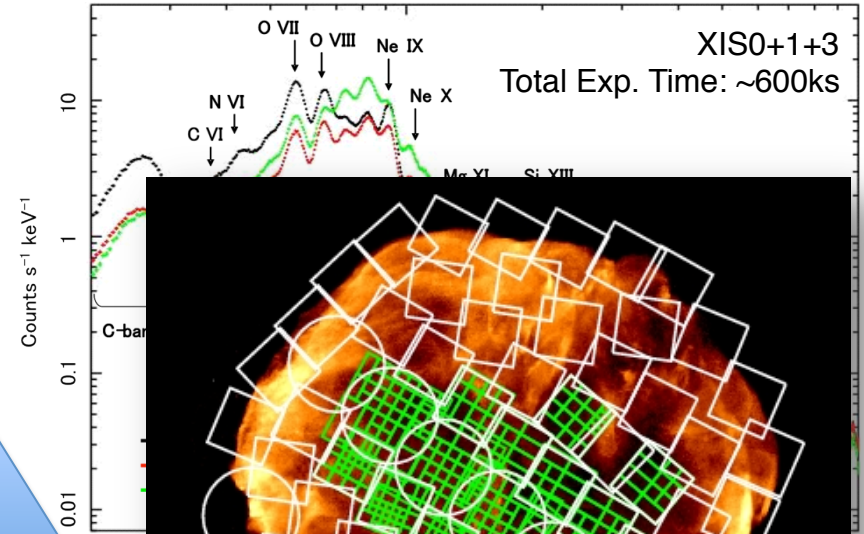

- **Introduction**
  - Classical fit with a conventional thin thermal model
- **Panoramic X-ray View of the Cygnus Loop**
  - Metallicity structures of the ejecta
  - North-South inhomogeneity of the heavy element
- **“Deep” Observation of the Cygnus Loop**
  - Unknown excess at 0.7keV
  - 1.2keV (missing) line problem
- **Summary**

ISM abundance  
Ejecta abundance

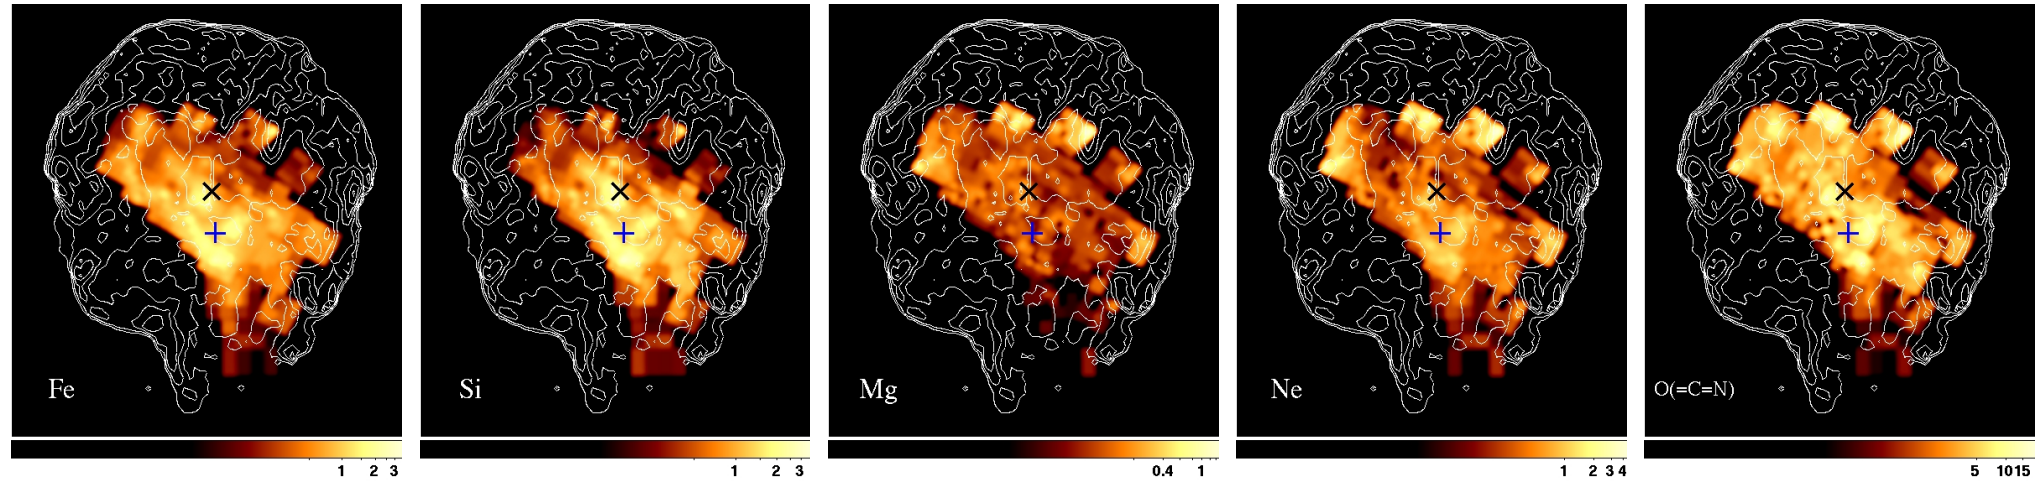

# Abundance vs. Abundance Plot

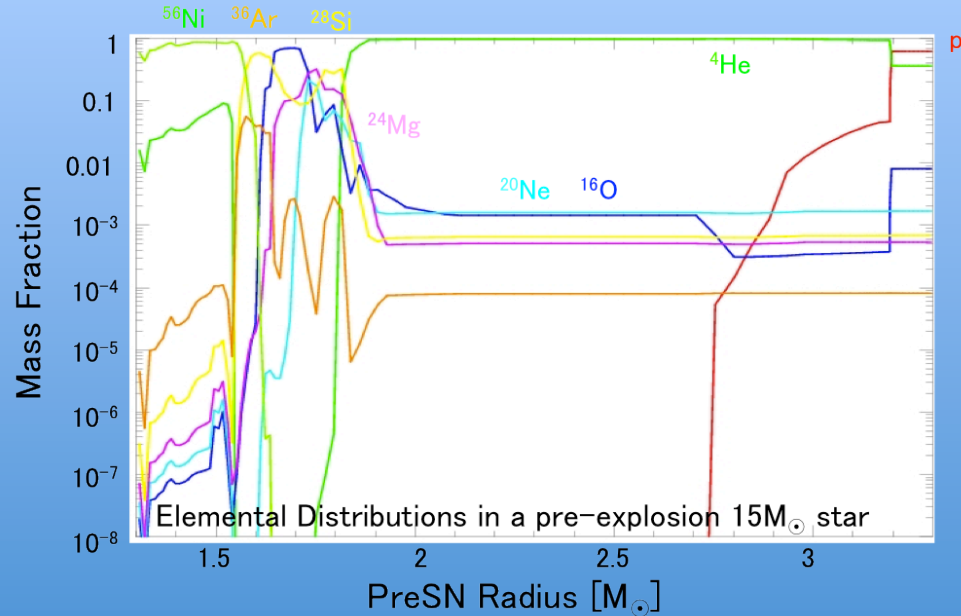

# “Onion-like” Structures of the Cygnus Loop

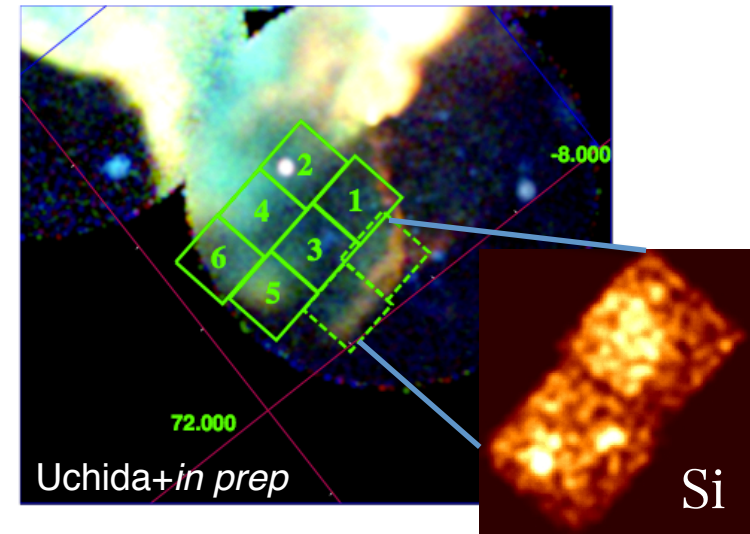

Uchida+2009b

## Mass fraction of $15M_{\odot}$ star before SN

# The heavy elements blew out to South?

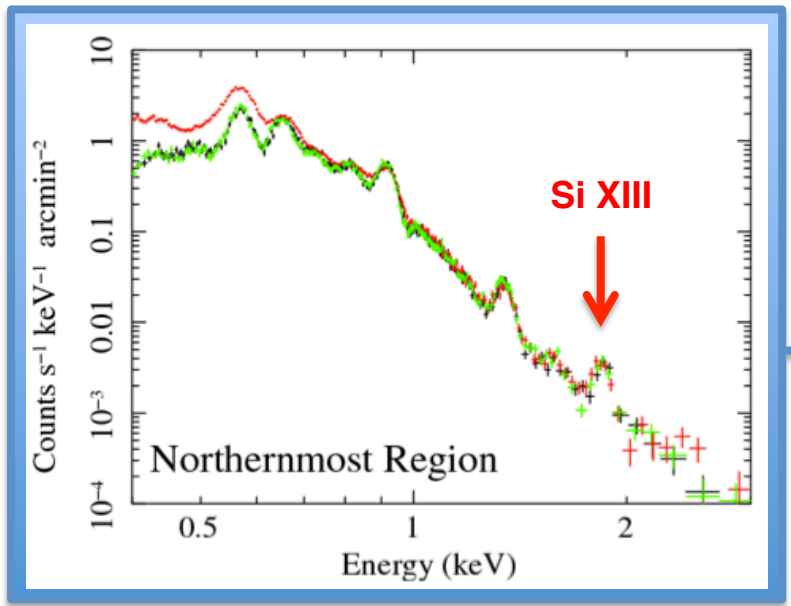

Si (and Fe) distribution Center shifts toward the South?

We have observed the blowout region with Suzaku (in AO5 and AO6 phases).

# North-South Inhomogeneity of the Heavy Element

Si Abundance:  
 $0.41 \pm 0.05$   
 Si/O:  $\sim 1$   
 Fe/O:  $\sim 0.5$

❖ The Si abundance in the southernmost region is **ten times higher** than that in the northernmost region.

Si Abundance:  
 $4.2 \pm 0.6$   
 Si/O: 10-30  
 Fe/O: 2-3

❖ Example: “SASI-aided” SN simulation of 15M<sub>⊙</sub> progenitor (Marek & Janka 2005).  
 ❖ Many theories estimate that the heavy elements eject in one direction.

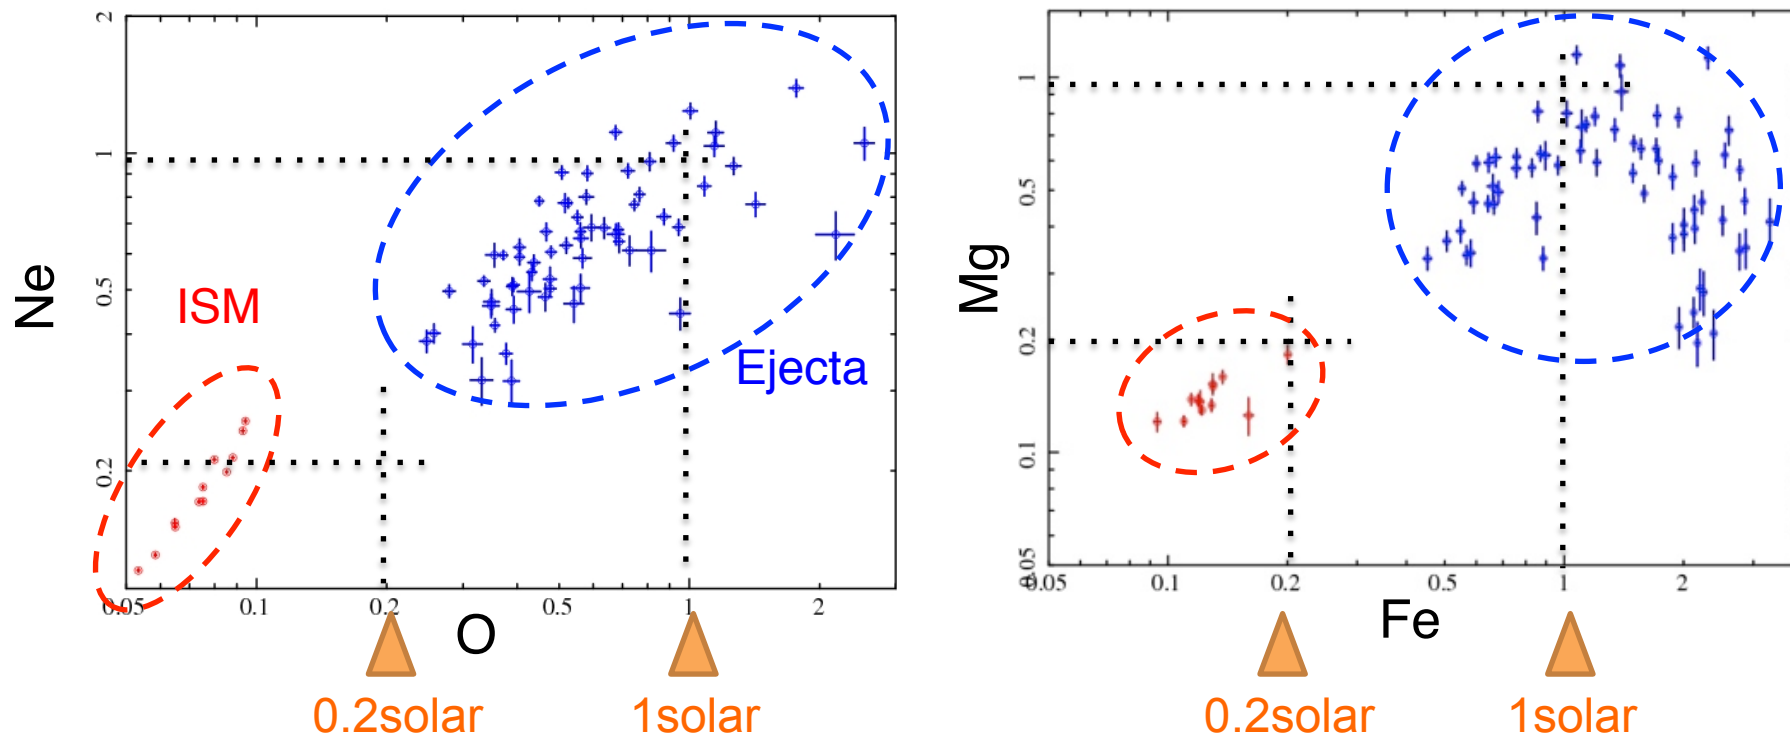

We are analyzing all the available data to reveal the whole picture of the ejecta structure.

# Outline

- Introduction
  - Classical fit with a conventional thin thermal model
- Panoramic X-ray View of the Cygnus Loop
  - Metallicity structures of the ejecta
  - North-South inhomogeneity of the heavy element
- **“Deep” Observation of the Cygnus Loop**
  - Unknown excess at 0.7keV – Possible charge exchange emission
  - 1.2keV (missing) line problem
- Summary

# Low abundance problem of the ISM component

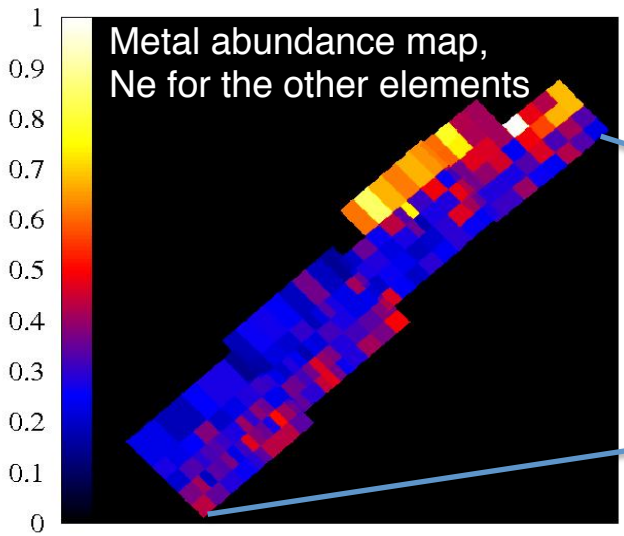

- ❖ The ISM abundances are significantly lower than the solar abundances.
- ❖ Such low abundance ISMs have been reported from some other SNRs;

Puppis A:  
RCW86:  
Vela SNR:

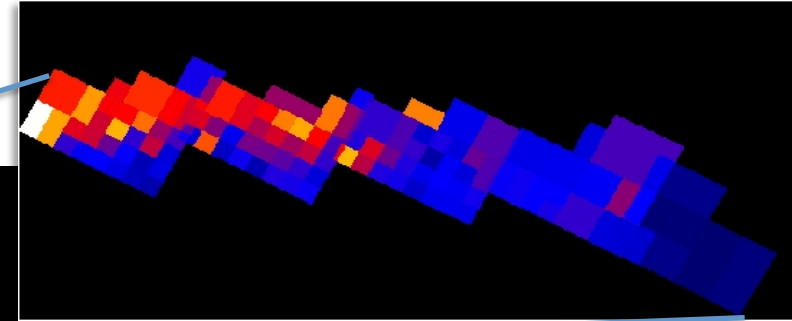

Hwang et al. 2008  
Yamaguchi et al. 2008  
Miceli et al. 2008

# Abundance Enhancement in the Cygnus Loop Rim

Katsuda+2008

Uchida+2009c

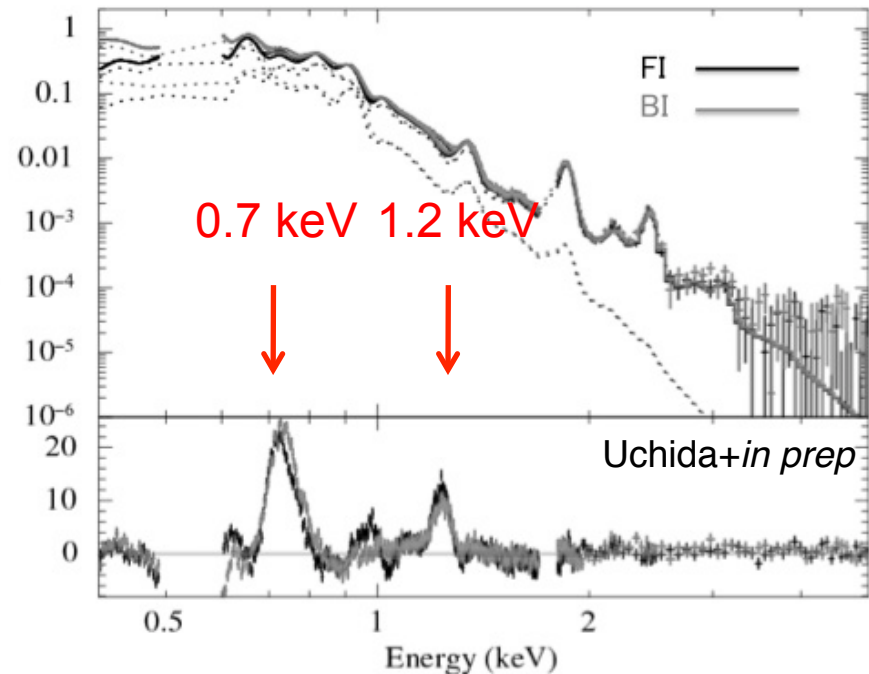

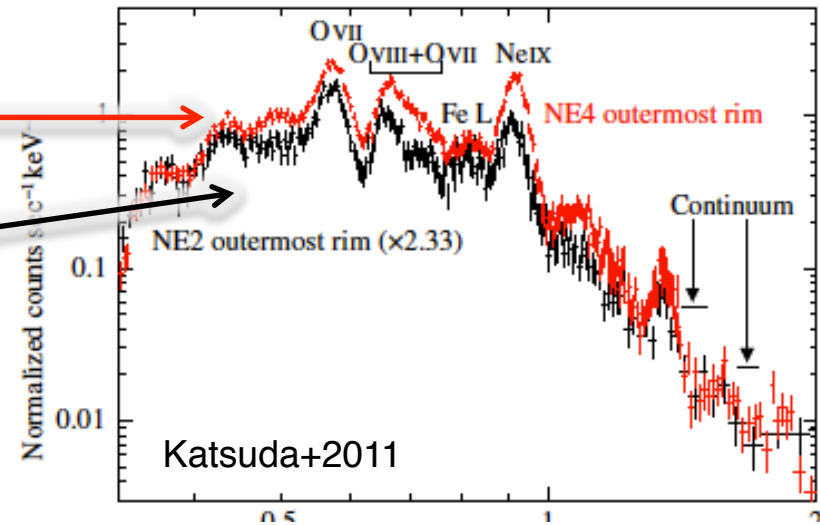

Blue region: ~0.2 solar  
Orange region: ~1 solar

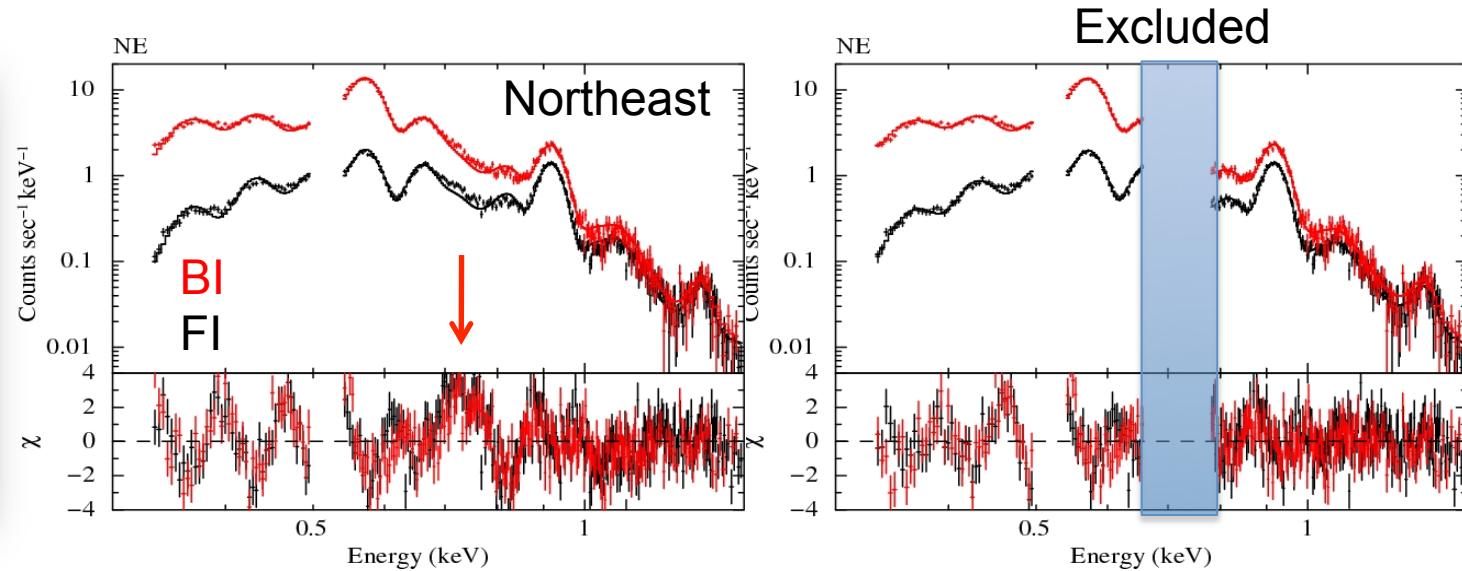

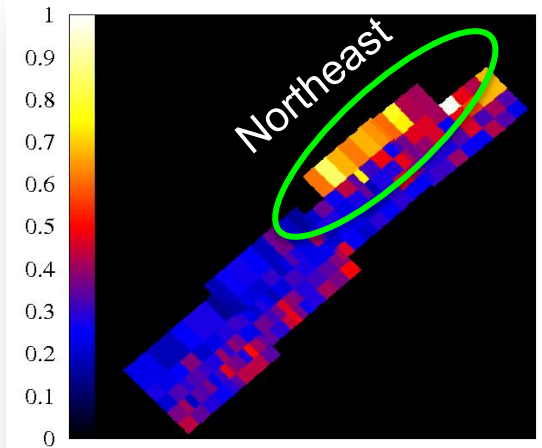

Tsunemi+2009  
Kosugi+2010

- ❖ Why the abundance distributions are inhomogeneous?
- ❖ What is the difference of the spectra between them?

# Fitting problems @ 0.7 keV and 1.2 keV in the current NEI model

# Refit excluding the 0.7 keV excess (Katsuda et al. 2011)

- ❖ When we exclude the excess at around 0.7 keV, the values of the abundances decreased significantly.
- ❖ The abundance inhomogeneity is resolved. However, what is the origin of the excess which faked the abundance enhancement?

$N_{\text{H}}$ :  $3 \times 10^{20}$  (fixed)  
 $kT_e$ : 0.31 (0.29-0.33)  
 $\text{Log}(n_e t)$ : 10.8 (10.7-10.9)  
 C: 1.2 (0.9-1.4)  
 N: 1.2 (0.9-1.5)  
 O: 0.6 (0.4-0.7)  
 Ne: 0.9 (0.7-1.1)  
 Mg: 0.3 (0.2-0.4)  
 Fe: 0.5 (0.4-0.6)  
 $\chi^2/\text{dof}$ : 1353/531

$N_{\text{H}}$ :  $3 \times 10^{20}$  (fixed)  
 $kT_e$ : 0.22 (0.21-0.23)  
 $\text{Log}(n_e t)$ : 11.4 (11.3-11.5)  
 C: 0.45 (0.38-0.50)  
 N: 0.49 (0.42-0.54)  
 O: 0.26 (0.23-0.27)  
 Ne: 0.59 (0.53-0.63)  
 Mg: 0.22 (0.17-0.26)  
 Fe: 0.23 (0.20-0.26)  
 $\chi^2/\text{dof}$ : 758/463

# What is the origin of the excess@0.7 keV?

- Thermal Origin?

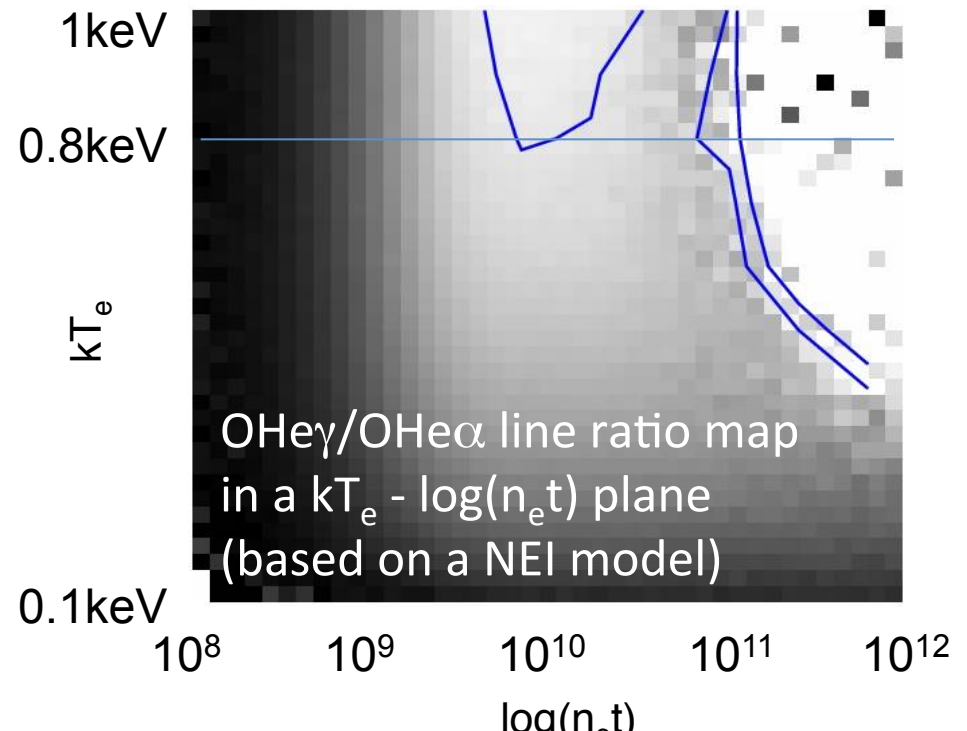

- Fe XVII L ( $3s \rightarrow 2p$ : 730eV)

- He-like O  $K\gamma + K\delta + \dots$  (e.g., SN1006; Yamaguchi+2008)

→ He $\gamma$  / He $\alpha$  ratio ( $\sim 0.045$ ) requires a very high temperature.

Flux ratio of X to O He $\alpha$  : 0.041-0.049

# Abundance vs. EW@0.7 keV Plot in the Cygnus Loop

- ❖ No correlations are found.
- ❖ The observed excess is not likely to be a thermal origin.

# What is the origin of the excess@0.7 keV?

- Thermal Origin?

- Fe XVII L ( $3s \rightarrow 2p$ : 730eV)

- He-like O  $K\gamma + K\delta + \dots$  (e.g., SN1006; Yamaguchi+2008)

→ He $\gamma$  / He $\alpha$  ratio ( $\sim 0.041-0.049$ ) requires a very high temperature.

Flux ratio of X to O He $\alpha$  : 0.041-0.049

# What is the origin of the excess@0.7 keV?

- Thermal Origin?
  - Fe L lines (3s→2p: 730eV, 3d→2p: 820eV)
  - He-like O K $\gamma$ +K $\delta$ +... (e.g., SN1007; )
- He-like O K cascade?
  - Recombining Plasma (Yamaguchi-san's talk)
    - No RRC feature is found in the Cygnus Loop spectra.
  - Photoionized Plasma (e.g, Cyg X-3; Kawashima & Kitamoto 1996)
    - There are no strong X-ray sources around the Cygnus Loop.
  - **Charge Exchange (Katsuda et al. 2011)**

Lallement (2004) claimed that charge exchange emission could be significant at narrow regions just behind shocks.

# Charge Exchange Region in the Cygnus Loop

Katsuda+2008

Uchida+2009c

❖ The excesses@0.7keV are found **only in some rims** and **only their outermost part.**

Levenson+1998

**We propose that the excess at 0.7 keV is due to a charge-exchange emission. (Katsuda et al. 2011)**

# Fitting problems @ 0.7 keV and 1.2 keV in the current NEI model

# “1.2keV (missing) line problem”

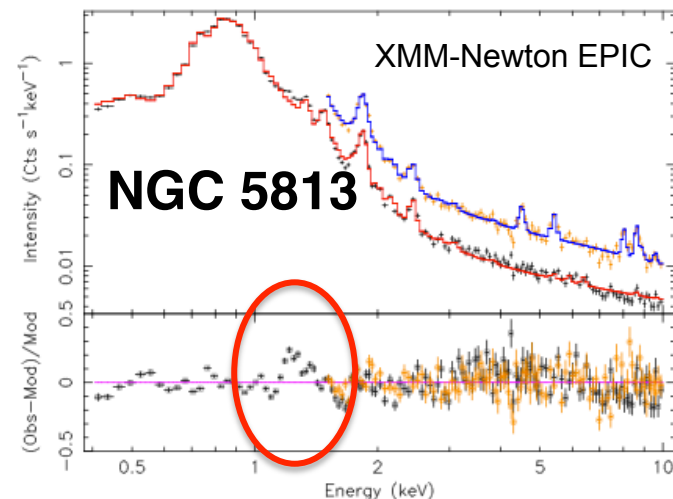

Hughes Hayashi & Koyama  
1998 *ApJ* **505** 732

Yamaguchi & Katsuda 2009  
*ApJ* **696** 1548

Grange et al. 2011 *submitted*

Brickhouse et al. 2000  
*ApJ* **530** 387

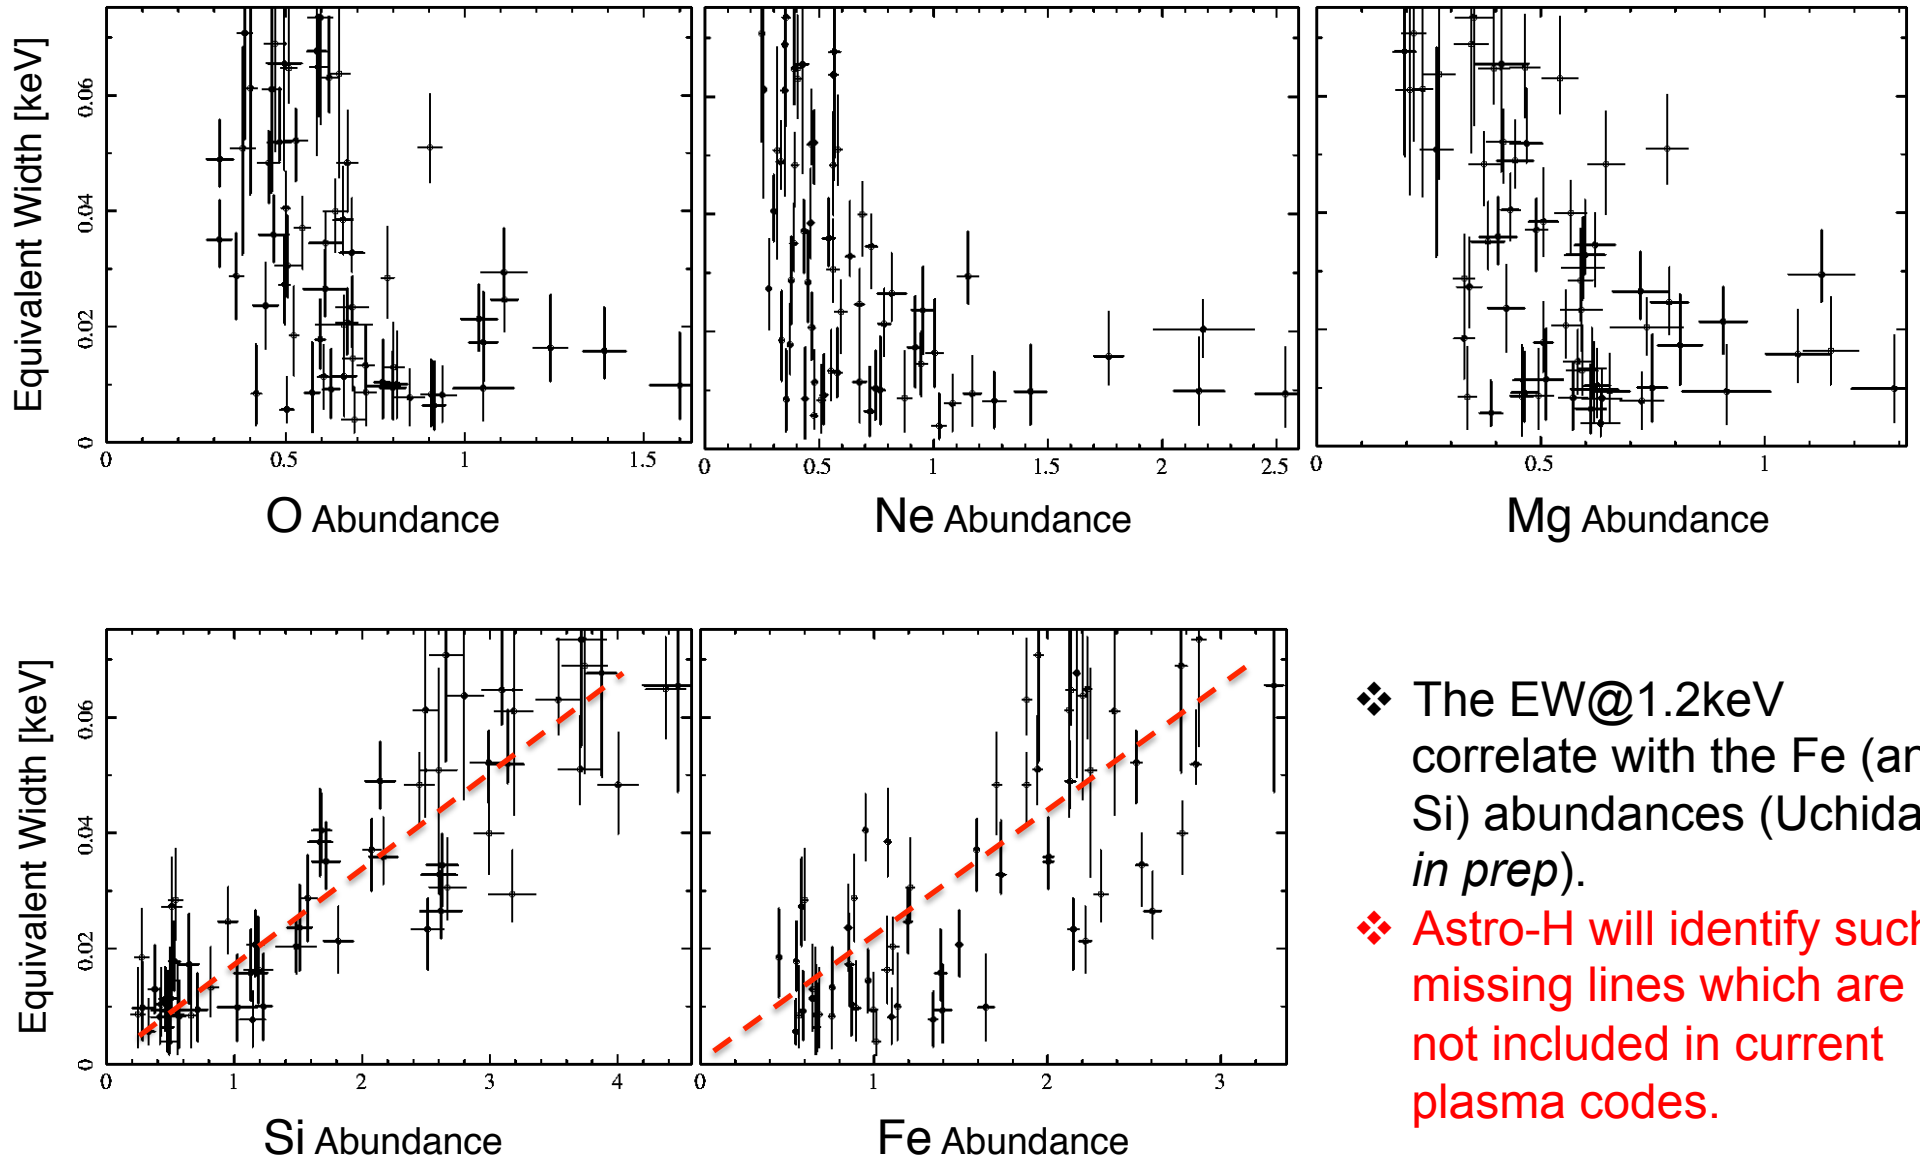

Miller et al. @ IACHEC 2011

- ❖ The missing line problem at 1.2 keV is often seen in many spectra with many detectors.
- ❖ Most of their sources are “Fe-rich”, which strongly suggests that these lines originate from a missing F-L line.

# Correlations between the EW@1.2 keV and elemental abundances

- ❖ The EW@1.2keV correlate with the Fe (and Si) abundances (Uchida+ *in prep*).
- ❖ Astro-H will identify such missing lines which are not included in current plasma codes.

# Summary

- We have observed the Cygnus Loop with Suzaku and XMM-Newton. The total exposure time reaches into  $\sim 1.7$  Ms.
- The ejecta structure show a clear “onion-like” structure. The heavy elements such as Si and Fe are much more abundant in the south toward the blowout region.
- We found that the spectra obtained from the enhanced-abundance regions have an excess at 0.7 keV.
- By considering various possibilities, we concluded that the excess at 0.7 keV originates from the charge-exchange emission at the outermost rim of the Loop.
- We also found a line-like feature at 1.2 keV and concluded the line originates from a missing Fe L line which is not included in the current plasma code.
- Astro-H SXS will be a key instrument to confirm the presence of charge exchange emission and a missing Fe L line at 1.2 keV.
